

CALM plaques
look like series
of puncta

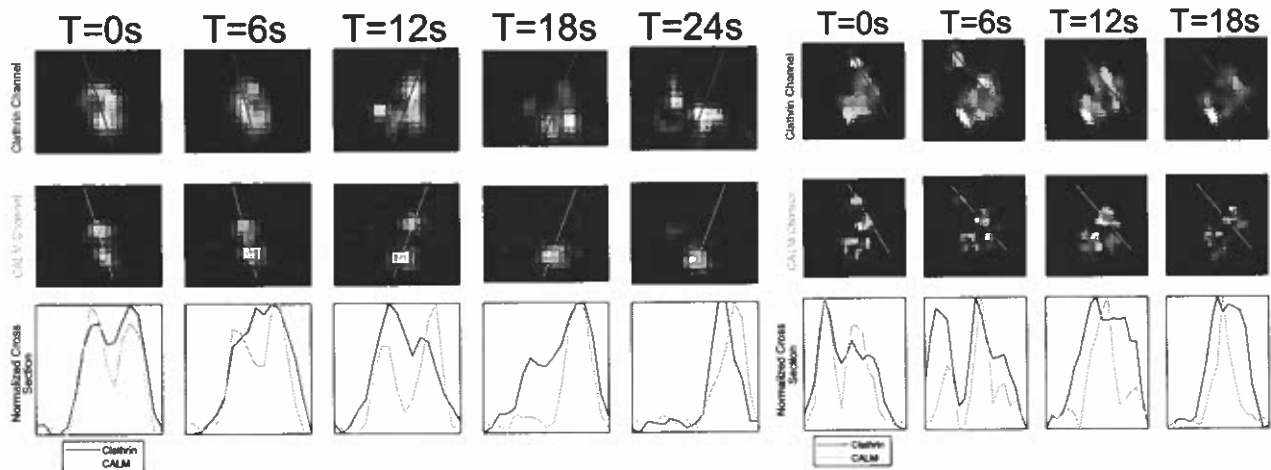

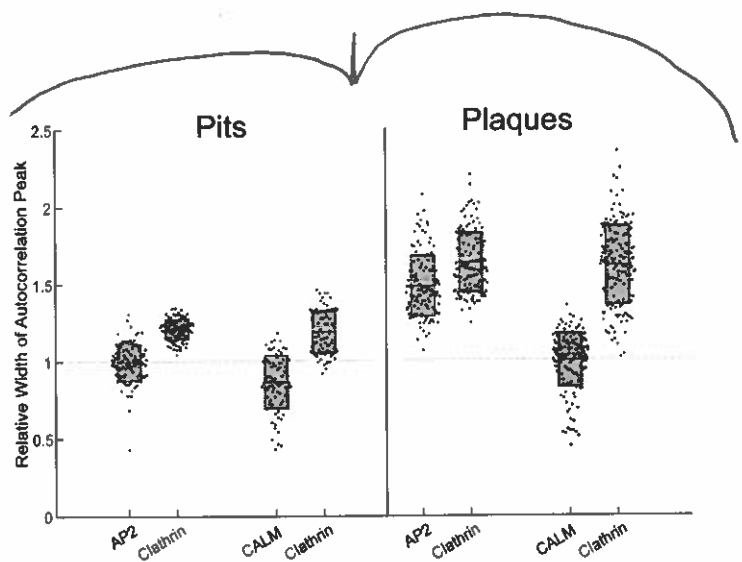

You can see this
by autocorrelation
analysis

The autocorrelation
peak is narrower

The finding on the right is general, not just for
these 2 structures. But this doesn't hold for pits

Same not
true for
AP2

Two examples of one of the CALM
puncta internalizing separately from the
rest of the plaque.

Suggesting they might be highly-curved
regions close to internalization.
